

# Package ‘gmm’

August 12, 2022

**Version** 1.7

**Date** 2022-07-30

**Title** Generalized Method of Moments and Generalized Empirical Likelihood

**Author** Pierre Chausse <pchausse@uwaterloo.ca>

**Maintainer** Pierre Chausse <pchausse@uwaterloo.ca>

## Description

It is a complete suite to estimate models based on moment conditions. It includes the two step Generalized method of moments (Hansen 1982; <doi:10.2307/1912775>), the iterated GMM and continuous updated estimator (Hansen, Eaton and Yaron 1996; <doi:10.2307/1392442>) and several methods that belong to the Generalized Empirical Likelihood family of estimators (Smith 1997; <doi:10.1111/j.0013-0133.1997.174.x>, Kitamura 1997; <doi:10.1214/aos/1069362388>, Newey and Smith 2004; <doi:10.1111/j.1468-0262.2004.00482.x>, and Anatolyev 2005 <doi:10.1111/j.1468-0262.2005.00601.x>).

**Depends** R (>= 2.10.0), sandwich

**NeedsCompilation** yes

**Suggests** knitr, mvtnorm, car, stabledist, MASS, timeDate, timeSeries

**Imports** stats, methods, grDevices, graphics

**License** GPL (>= 2)

**VignetteBuilder** knitr

**Repository** CRAN

**Repository/R-Forge/Project** gmm

**Repository/R-Forge/Revision** 203

**Repository/R-Forge/DateTimeStamp** 2022-08-12 02:50:41

**Date/Publication** 2022-08-12 12:40:02 UTC

ATEgel

*ATE with Generalized Empirical Likelihood estimation*

---

## Description

Function to estimate the average treatment effect with the sample being balanced by GEL.

## Usage

```
ATEgel(g, balm, w=NULL, y=NULL, treat=NULL, tet0=NULL, momType=c("bal", "balSample", "ATT"),
       popMom = NULL, family=c("linear", "logit", "probit"),
       type = c("EL", "ET", "CUE", "ETEL", "HD", "ETHD", "RCUE"),
       tol_lam = 1e-9, tol_obj = 1e-9, tol_mom = 1e-9, maxiterlam = 100,
       optfct = c("optim", "nlnminb"),
       optlam = c("nlnminb", "optim", "iter", "Wu"), data=NULL,
```

```

Lambdacontrol = list(),
model = TRUE, X = FALSE, Y = FALSE, ...)
checkConv(obj, tolConv=1e-4, verbose=TRUE, ...)

```

### Arguments

g	A formula as $y \sim z$ , where codey is the response and z the treatment indicator. If there is more than one treatment, more indicators can be added or z can be set as a factor. It can also be of the form $g(\text{theta}, y, z)$ for non-linear models. It is however, not implemented yet.
obj	Object of class "ategel" produced by ATEgel
balM	A formula for the moments to be balanced between the treated and control groups (see details)
y	The response variable when g is a function. Not implemented yet
treat	The treatment indicator when g is a function. Not implemented yet
w	A formula to add covariates to the main regression. When NULL, the default value, the main regression only include treatment indicators.
tet0	A $3 \times 1$ vector of starting values. If not provided, they are obtained using an OLS regression
momType	How the moments of the covariates should be balanced. By default, it is simply balanced without restriction. Alternatively, moments can be set equal to the sample moments of the whole sample, or to the sample moments of the treated group. The later will produce the average treatment effect of the treated (ATT)
popMom	A vector of population moments to use for balancing. It can be used if those moments are available from a census, for example. When available, it greatly improves efficiency.
family	By default, the outcome is linearly related to the treatment indicators. If the outcome is binary, it is possible to use the estimating equations of either the logit or probit model.
type	"EL" for empirical likelihood, "ET" for exponential tilting, "CUE" for continuous updated estimator, "ETEL" for exponentially tilted empirical likelihood of Schennach(2007), "HD" for Hellinger Distance of Kitamura-Otsu-Evdokimov (2013), and "ETHD" for the exponentially tilted Hellinger distance of Antoine-Dovonon (2015). "RCUE" is a restricted version of "CUE" in which the probabilities are bounded below by zero. In that case, an analytical Kuhn-Tucker method is used to find the solution.
tol_lam	Tolerance for $\lambda$ between two iterations. The algorithm stops when $\ \lambda_i - \lambda_{i-1}\ $ reaches tol_lamb (see <a href="#">getLamb</a> )
maxiterlam	The algorithm to compute $\lambda$ stops if there is no convergence after "maxiterlam" iterations (see <a href="#">getLamb</a> ).
tol_obj	Tolerance for the gradient of the objective function to compute $\lambda$ (see <a href="#">getLamb</a> ).
optfct	Algorithm used for the parameter estimates
tol_mom	It is the tolerance for the moment condition $\sum_{t=1}^n p_t g(\theta(x_t)) = 0$ , where $p_t = \frac{1}{n} D\rho(\langle g_t, \lambda \rangle)$ is the implied probability. It adds a penalty if the solution diverges from its goal.

optlam	Algorithm used to solve for the lagrange multiplier in <code>getLamb</code> . The algorithm Wu is only for <code>type="EL"</code> . The value of <code>optLam</code> is ignored for "CUE" because in that case, the analytical solution exists.
data	A <code>data.frame</code> or a matrix with column names (Optional).
Lambdacontrol	Controls for the optimization of the vector of Lagrange multipliers used by either <code>optim</code> , <code>nlminb</code> or <code>constrOptim</code>
model, X, Y	logicals. If TRUE the corresponding components of the fit (the model frame, the model matrix, the response) are returned if <code>g</code> is a formula.
verbose	If TRUE, a summary of the convergence is printed
tolConv	The tolerance for comparing moments between groups
...	More options to give to <code>optim</code> or <code>nlminb</code> . In <code>checkConv</code> , they are options passed to <code>getImpProb</code> .

### Details

We want to estimate the model  $Y_t = \theta_1 + \theta_2 \text{treat} + \epsilon_t$ , where  $\theta_2$  is the treatment effect. GEL is used to balance the sample based on the argument `x` above.

For example, if we want the sample mean of `x1` and `x2` to be balanced between the treated and control, we set `x` to `~x1+x2`. If we want the sample mean of `x1`, `x2`, `x1*x2`, `x1^2` and `x2^2`, we set `x` to `~x1*x2 + I(x1^2) + I(x2^2)`.

### Value

'`gel`' returns an object of 'class' "`ategel`"

The functions '`summary`' is used to obtain and print a summary of the results.

The object of class "`ategel`" is a list containing the same elements contained in objects of class `gel`.

### Examples

```
data(nsw)
# Scale income
nsw$re78 <- nsw$re78/1000
nsw$re75 <- nsw$re75/1000
```

```

res <- ATEgel(re78~treat, ~age+ed+black+hispanic+married+nodeg+re75,
data=nsw,type="ET")
summary(res)
chk <- checkConv(res)

res2 <- ATEgel(re78~treat, ~age+ed+black+hispanic+married+nodeg+re75,
data=nsw,type="ET", momType="balSample")
summary(res2)
chk2 <- checkConv(res2)

```

---

bread	<i>Bread for sandwiches</i>
-------	-----------------------------

---

## Description

Computes the bread of the sandwich covariance matrix

## Usage

```

## S3 method for class 'gmm'
bread(x, ...)
## S3 method for class 'gel'
bread(x, ...)
## S3 method for class 'tsls'
bread(x, ...)

```

## Arguments

x	A fitted model of class gmm or gel.
...	Other arguments when bread is applied to another class object

## Details

When the weighting matrix is not the optimal one, the covariance matrix of the estimated coefficients is:  $(G'WG)^{-1}G'WVWG(G'WG)^{-1}$ , where  $G = d\bar{g}/d\theta$ ,  $W$  is the matrix of weights, and  $V$  is the covariance matrix of the moment function. Therefore, the bread is  $(G'WG)^{-1}$ , which is the second derivative of the objective function.

The method is not yet available for gel objects.

## Value

A  $k \times k$  matrix (see details).

## References

Zeileis A (2006), Object-oriented Computation of Sandwich Estimators. *Journal of Statistical Software*, **16**(9), 1–16. URL [doi:10.18637/jss.v016.i09](https://doi.org/10.18637/jss.v016.i09).

## Examples

```
# See \link{gmm} for more details on this example.
# With the identity matrix
# bread is the inverse of (G'G)

n <- 1000
x <- rnorm(n, mean = 4, sd = 2)
g <- function(tet, x)
  {
    m1 <- (tet[1] - x)
    m2 <- (tet[2]^2 - (x - tet[1])^2)
    m3 <- x^3 - tet[1]*(tet[1]^2 + 3*tet[2]^2)
    f <- cbind(m1, m2, m3)
    return(f)
  }
Dg <- function(tet, x)
  {
    jacobian <- matrix(c( 1, 2*(-tet[1]+mean(x)), -3*tet[1]^2-3*tet[2]^2, 0, 2*tet[2],
-6*tet[1]*tet[2]), nrow=3,ncol=2)
    return(jacobian)
  }

res <- gmm(g, x, c(0, 0), grad = Dg,weightsMatrix=diag(3))
G <- Dg(res$coef, x)
bread(res)
solve(crossprod(G))
```

---

 bwWilhelm

*Wilhelm (2015) bandwidth selection*

---

## Description

It computes the optimal bandwidth for the HAC estimation of the covariance matrix of the moment conditions. The bandwidth was shown by Wilhelm (2005) to be the one that minimizes the MSE of the GMM estimator.

## Usage

```
bwWilhelm(x, order.by = NULL, kernel = c("Quadratic Spectral",
"Bartlett", "Parzen", "Tukey-Hanning"), approx = c("AR(1)", "ARMA(1,1)"),
weights = NULL, prewhite = 1, ar.method = "ols", data = list())
```

## Arguments

x	An object of class <code>gmm</code> .
order.by	Either a vector 'z' or a formula with a single explanatory variable like '~z'. The observations in the model are ordered by the size of 'z'. If set to 'NULL' (the default) the observations are assumed to be ordered (e.g., a time series).

kernel	type of kernel used to compute the covariance matrix of the vector of sample moment conditions (see <a href="#">kernHAC</a> for more details)
approx	A character specifying the approximation method if the bandwidth has to be chosen by bwAndrews.
weights	numeric. A vector of weights used for weighting the estimated coefficients of the approximation model (as specified by 'approx'). By default all weights are 1 except that for the intercept term (if there is more than one variable)
prewhite	logical or integer. Should the estimating functions be prewhitened? If TRUE or greater than 0 a VAR model of order as.integer(prewhite) is fitted via ar with method "ols" and demean = FALSE.
ar.method	character. The method argument passed to <a href="#">ar</a> for prewhitening.
data	an optional data frame containing the variables in the 'order.by' model.

### Value

The function 'bwWilhelm' returns the optimal bandwidth.

### Note

The function was written by Daniel Wilhelm and is based on [bwAndrews](#).

### Examples

```
data(Finance)
f1 <- Finance[1:300, "rm"]
f2 <- Finance[1:300, "hml"]
f3 <- Finance[1:300, "smb"]
y <- Finance[1:300, "WMK"]

## Silly example just to make it over-identified
#####
res <- gmm(y ~ f1, ~ f1 + f2 + f3)
summary(res)

## Set the bandwidth using the second step estimate
#####
bw <- bwWilhelm(res)
res2 <- update(res, bw=bw)
summary(res2)

## Set the bandwidth using the first-step estimate as for bwAndrews
```

```
#####
res3 <- gmm(y ~ f1, ~ f1 + f2 + f3, bw=bwWilhelm)
summary(res3)
```

---

charStable

*The characteristic function of a stable distribution*

---

### Description

It computes the theoretical characteristic function of a stable distribution for two different parametrizations. It is used in the vignette to illustrate the estimation of the parameters using GMM.

### Usage

```
charStable(theta, tau, pm = 0)
```

### Arguments

theta	Vector of parameters of the stable distribution. See details.
tau	A vector of numbers at which the function is evaluated.
pm	The type of parametrization. It takes the values 0 or 1.

### Details

The function returns the vector  $\Psi(\theta, \tau, pm)$  defined as  $E(e^{ix\tau})$ , where  $\tau$  is a vector of real numbers,  $i$  is the imaginary number,  $x$  is a stable random variable with parameters  $\theta = (\alpha, \beta, \gamma, \delta)$  and  $pm$  is the type of parametrization. The vector of parameters are the characteristic exponent, the skewness, the scale and the location parameters, respectively. The restrictions on the parameters are:  $\alpha \in (0, 2]$ ,  $\beta \in [-1, 1]$  and  $\gamma > 0$ . For more details see Nolan(2009).

### Value

It returns a vector of complex numbers with the dimension equals to `length(tau)`.

### References

Nolan J. P. (2020), Univariate Stable Distributions - Models for Heavy Tailed Data. *Springer Series in Operations Research and Financial Engineering*. URL <https://edspace.american.edu/jpnolan/stable/>.

**Examples**

```
# GMM is like GLS for linear models without endogeneity problems

pm <- 0
theta <- c(1.5,.5,1,0)
tau <- seq(-3, 3, length.out = 20)
char_fct <- charStable(theta, tau, pm)
```

---

coef	<i>Coefficients of GEL or GMM</i>
------	-----------------------------------

---

**Description**

It extracts the coefficients from `gel` or `gmm` objects.

**Usage**

```
## S3 method for class 'gmm'
coef(object, ...)
## S3 method for class 'gel'
coef(object, lambda = FALSE, ...)
```

**Arguments**

object	An object of class <code>gel</code> or <code>gmm</code> returned by the function <code>gel</code> or <code>gmm</code>
lambda	If set to <code>TRUE</code> , the lagrange multipliers are extracted instead of the vector of coefficients
...	Other arguments when <code>coef</code> is applied to an other class object

**Value**

Vector of coefficients

**Examples**

```
#####
n = 500
phi<-c(.2,.7)
thet <- 0
sd <- .2
x <- matrix(arima.sim(n=n,list(order=c(2,0,1),ar=phi,ma=thet,sd=sd)),ncol=1)
y <- x[7:n]
ym1 <- x[6:(n-1)]
ym2 <- x[5:(n-2)]
```

```

H <- cbind(x[4:(n-3)], x[3:(n-4)], x[2:(n-5)], x[1:(n-6)])
g <- y ~ ym1 + ym2
x <- H
t0 <- c(0,.5,.5)

res <- gel(g, x, t0)

coef(res)
coef(res, lambda = TRUE)
#####
res <- gmm(g, x)
coef(res)

```

---

confint

*Confidence intervals for GMM or GEL*

---

## Description

It produces confidence intervals for the coefficients from `gel` or `gmm` estimation.

## Usage

```

## S3 method for class 'gel'
confint(object, parm, level = 0.95, lambda = FALSE,
        type = c("Wald", "invLR", "invLM", "invJ"),
        fact = 3, corr = NULL, ...)

## S3 method for class 'gmm'
confint(object, parm, level = 0.95, ...)

## S3 method for class 'ategel'
confint(object, parm, level = 0.95, lambda = FALSE,
        type = c("Wald", "invLR", "invLM", "invJ"), fact = 3,
        corr = NULL, robToMiss=TRUE, ...)

## S3 method for class 'confint'
print(x, digits = 5, ...)

```

## Arguments

<code>object</code>	An object of class <code>gel</code> or <code>gmm</code> returned by the function <code>gel</code> or <code>gmm</code>
<code>parm</code>	A specification of which parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all parameters are considered.
<code>level</code>	The confidence level
<code>lambda</code>	If set to <code>TRUE</code> , the confidence intervals for the Lagrange multipliers are produced.
<code>type</code>	'Wald' is the usual symmetric confidence interval. The three others are based on the inversion of the LR, LM, and J tests.

fact	This parameter control the span of search for the inversion of the test. By default we search within plus or minus 3 times the standard error of the coefficient estimate.
corr	This numeric scalar is meant to apply a correction to the critical value, such as a Bartlett correction. This value depends on the model (See Owen; 2001)
x	An object of class confint produced by confint.gel and confint.gmm
digits	The number of digits to be printed
robToMiss	If TRUE, the confidence interval is based on the standard errors that are robust to misspecification
...	Other arguments when confint is applied to another classe object

### Value

It returns a matrix with the first column being the lower bound and the second the upper bound.

```

---

estfun

*Extracts the empirical moment function*

---

## Description

It extracts the matrix of empirical moments so that it can be used by the [kernHAC](#) function.

## Usage

```

## S3 method for class 'gmmFct'
estfun(x, y = NULL, theta = NULL, ...)
## S3 method for class 'gmm'
estfun(x, ...)
## S3 method for class 'gel'
estfun(x, ...)
## S3 method for class 'tsls'
estfun(x, ...)
## S3 method for class 'tsls'
model.matrix(object, ...)

```

## Arguments

**x** A function of the form  $g(\theta, y)$  or a  $n \times q$  matrix with typical element  $g_i(\theta, y_t)$  for  $i = 1, \dots, q$  and  $t = 1, \dots, n$  or an object of class `gmm`. See [gmm](#) for more details. For `tsls`, it is an object of class `tsls`.

object	An object of class <code>tsls</code> .
y	The matrix or vector of data from which the function $g(\theta, y)$ is computed if <code>g</code> is a function.
theta	Vector of parameters if <code>g</code> is a function.
...	Other arguments when <code>estfun</code> is applied to another class object

### Details

For `estfun.gmmFct`, it returns a  $n \times q$  matrix with typical element  $g_i(\theta, y_t)$  for  $i = 1, \dots, q$  and  $t = 1, \dots, n$ . It is only used by `gmm` to obtain the estimates.

For `estfun.gmm`, it returns the matrix of first order conditions of  $\min_{\theta} \bar{g}'W\bar{g}/2$ , which is a  $n \times k$  matrix with the  $t^{\text{th}}$  row being  $g(\theta, y_t)WG$ , where  $G$  is  $d\bar{g}/d\theta$ . It allows to compute the sandwich covariance matrix using `kernHAC` or `vcovHAC` when  $W$  is not the optimal matrix.

The method is not yet available for `ge1` objects.

For `tsls`, `model.matrix` and `estfun` are used by `vcov()` to compute different covariance matrices using the `sandwich` package. See `vcov.tsls`. `model.matrix` returns the fitted values from the first stage regression and `estfun` the residuals.

### Value

A  $n \times q$  matrix (see details).

 Finance

*Returns on selected stocks*

---

### Description

Daily returns on selected stocks, the Market portfolio and factors of Fama and French from 1993-01-05 to 2009-01-30 for CAPM and APT analysis

### Usage

```
data(Finance)
```

### Format

A data frame containing 24 time series. Dates are reported as rownames(). In the following description, company symbols are used.

**WMK** Returns of WEIS MARKETS INC

**UIS** Returns of UNISYS CP NEW

**ORB** Returns of ORBITAL SCIENCES CP

**MAT** Returns of Mattel, Inc.

**ABAX** Returns of ABAXIS, Inc.

**T** Returns of AT&T INC.

---

 FinRes

---

*Method to finalize the result of the momentEstim method*

---

**Description**

It computes the final results that will be needed to create the object of class gmm.).

**Usage**

```
## S3 method for class 'baseGmm.res'
FinRes(z, object, ...)
```

**Arguments**

z	An object of class determined by the method momentEstim.
object	An object produced my getModel
...	Other argument to be passed to other FinRes methods.

**Value**

It returns an object of class gmm. See [gmm](#) for more details.

---

 fitted

---

*Fitted values of GEL and GMM*

---

**Description**

Method to extract the fitted values of the model estimated by [gel](#) or [gmm](#).

**Usage**

```
## S3 method for class 'gel'
fitted(object, ...)
## S3 method for class 'gmm'
fitted(object, ...)
```

**Arguments**

object            An object of class `gel` or `gel` returned by the function `gel` or `gmm`  
 ...                Other arguments when `fitted` is applied to an other class object

**Value**

It returns a matrix of the estimated mean  $\hat{y}$  in  $g=y\sim x$  as it is done by `fitted.lm`.

**Examples**

```
# GEL can deal with endogeneity problems

n = 200
phi<-c(.2,.7)
thet <- 0.2
sd <- .2
set.seed(123)
x <- matrix(arima.sim(n = n, list(order = c(2,0,1), ar = phi, ma = thet, sd = sd)), ncol = 1)

y <- x[7:n]
ym1 <- x[6:(n-1)]
ym2 <- x[5:(n-2)]
H <- cbind(x[4:(n-3)], x[3:(n-4)], x[2:(n-5)], x[1:(n-6)])
g <- y ~ ym1 + ym2
x <- H

res <- gel(g, x, c(0,.3,.6))
plot(y, main = "Fitted ARMA with GEL")
lines(fitted(res), col = 2)

# GMM is like GLS for linear models without endogeneity problems

set.seed(345)
n = 200
phi<-c(.2,.7)
thet <- 0
sd <- .2
x <- matrix(arima.sim(n = n, list(order = c(2,0,1), ar = phi, ma = thet, sd = sd)), ncol = 1)
y <- 10 + 5*rnorm(n) + x

res <- gmm(y ~ x, x)
plot(x, y, main = "Fitted model with GMM")
lines(x, fitted(res), col = 2)
legend("topright", c("Y", "Yhat"), col = 1:2, lty = c(1,1))
```

---

formula	<i>Formula method for gel and gmm objects</i>
---------	---

---

## Description

Method to extract the formula from gel or gmm objects.

## Usage

```
## S3 method for class 'gel'
formula(x, ...)
## S3 method for class 'gmm'
formula(x, ...)
```

## Arguments

`x` An object of class gel or gmm returned by the function [gel](#) or [gmm](#)  
`...` Other arguments to pass to other methods

## Examples

```
## GEL ##
n = 200
phi<-c(.2,.7)
thet <- 0.2
sd <- .2
set.seed(123)
x <- matrix(arima.sim(n = n, list(order = c(2,0,1), ar = phi, ma = thet, sd = sd)), ncol = 1)

y <- x[7:n]
ym1 <- x[6:(n-1)]
ym2 <- x[5:(n-2)]
H <- cbind(x[4:(n-3)], x[3:(n-4)], x[2:(n-5)], x[1:(n-6)])
g <- y ~ ym1 + ym2
x <- H

res <- gel(g, x, c(0,.3,.6))
formula(res)

# GMM is like GLS for linear models without endogeneity problems

set.seed(345)
n = 200
phi<-c(.2,.7)
thet <- 0
sd <- .2
x <- matrix(arima.sim(n = n, list(order = c(2,0,1), ar = phi, ma = thet, sd = sd)), ncol = 1)
y <- 10 + 5*rnorm(n) + x
```

```
res <- gmm(y ~ x, x)
formula(res)
```

gel

*Generalized Empirical Likelihood estimation***Description**

Function to estimate a vector of parameters based on moment conditions using the GEL method as presented by Newey-Smith(2004) and Anatolyev(2005).

**Usage**

```
gel(g, x, tet0 = NULL, gradv = NULL, smooth = FALSE,
    type = c("EL", "ET", "CUE", "ETEL", "HD", "ETHD", "RCUE"),
    kernel = c("Truncated", "Bartlett"), bw = bwAndrews,
    approx = c("AR(1)", "ARMA(1,1)"), prewhite = 1, ar.method = "ols",
    tol_weights = 1e-7, tol_lam = 1e-9, tol_obj = 1e-9, tol_mom = 1e-9,
    maxiterlam = 100, constraint = FALSE, optfct = c("optim", "optimize",
    "nlminb"), optlam = c("nlminb", "optim", "iter", "Wu"), data,
    Lambdacontrol = list(), model = TRUE, X = FALSE, Y = FALSE,
    TypeGel = "baseGel", alpha = NULL, eqConst = NULL,
    eqConstFullVcov = FALSE, onlyCoefficients=FALSE, ...)
evalGel(g, x, tet0, gradv = NULL, smooth = FALSE,
    type = c("EL", "ET", "CUE", "ETEL", "HD", "ETHD", "RCUE"),
    kernel = c("Truncated", "Bartlett"), bw = bwAndrews,
    approx = c("AR(1)", "ARMA(1,1)"), prewhite = 1,
    ar.method = "ols", tol_weights = 1e-7, tol_lam = 1e-9, tol_obj = 1e-9,
    tol_mom = 1e-9, maxiterlam = 100, optlam = c("nlminb", "optim",
    "iter", "Wu"), data, Lambdacontrol = list(),
    model = TRUE, X = FALSE, Y = FALSE, alpha = NULL, ...)
```

**Arguments**

- |      |  |
|------|--|
| g    | A function of the form $g(\theta, x)$ and which returns a $n \times q$ matrix with typical element $g_i(\theta, x_t)$ for $i = 1, \dots, q$ and $t = 1, \dots, n$ . This matrix is then used to build the $q$ sample moment conditions. It can also be a formula if the model is linear (see details below). |
| tet0 | A $k \times 1$ vector of starting values. If the dimension of $\theta$ is one, see the argument "optfct". In the linear case, if tet0=NULL, the 2-step gmm estimator is used as starting value. However, it has to be provided when eqConst is not NULL  |
| x    | The matrix or vector of data from which the function $g(\theta, x)$ is computed. If "g" is a formula, it is an $n \times Nh$ matrix of instruments (see details below).  |

gradv	A function of the form $G(\theta, x)$ which returns a $q \times k$ matrix of derivatives of $\bar{g}(\theta)$ with respect to $\theta$ . By default, the numerical algorithm <code>numericDeriv</code> is used. It is of course strongly suggested to provide this function when it is possible. This gradient is used to compute the asymptotic covariance matrix of $\hat{\theta}$ . If "g" is a formula, the gradient is not required (see the details below).
smooth	If set to TRUE, the moment function is smoothed as proposed by Kitamura(1997)
type	"EL" for empirical likelihood, "ET" for exponential tilting, "CUE" for continuous updated estimator, "ETEL" for exponentially tilted empirical likelihood of Schennach(2007), "HD" for Hellinger Distance of Kitamura-Otsu-Evdokimov (2013), and "ETHD" for the exponentially tilted Hellinger distance of Antoine-Dovonon (2015). "RCUE" is a restricted version of "CUE" in which the probabilities are bounded below by zero. In that case, an analytical Kuhn-Tucker method is used to find the solution.
kernel	type of kernel used to compute the covariance matrix of the vector of sample moment conditions (see <code>kernHAC</code> for more details) and to smooth the moment conditions if "smooth" is set to TRUE. Only two types of kernel are available. The truncated implies a Bartlett kernel for the HAC matrix and the Bartlett implies a Parzen kernel (see Smith 2004).
bw	The method to compute the bandwidth parameter. By default it is <code>bwAndrews</code> which is proposed by Andrews (1991). The alternative is <code>bwNeweyWest</code> of Newey-West(1994).
prewhite	logical or integer. Should the estimating functions be prewhitened? If TRUE or greater than 0 a VAR model of order <code>as.integer(prewhite)</code> is fitted via <code>ar</code> with method "ols" and <code>demean = FALSE</code> .
ar.method	character. The method argument passed to <code>ar</code> for prewhitening.
approx	a character specifying the approximation method if the bandwidth has to be chosen by <code>bwAndrews</code> .
tol_weights	numeric. Weights that exceed <code>tol</code> are used for computing the covariance matrix, all other weights are treated as 0.
tol_lam	Tolerance for $\lambda$ between two iterations. The algorithm stops when $\ \lambda_i - \lambda_{i-1}\ $ reaches <code>tol_lamb</code> (see <code>getLamb</code> )
maxiterlam	The algorithm to compute $\lambda$ stops if there is no convergence after "maxiterlam" iterations (see <code>getLamb</code> ).
tol_obj	Tolerance for the gradient of the objective function to compute $\lambda$ (see <code>getLamb</code> ).
optfct	Only when the dimension of $\theta$ is 1, you can choose between the algorithm <code>optim</code> or <code>optimize</code> . In that case, the former is unreliable. If <code>optimize</code> is chosen, "t0" must be $1 \times 2$ which represents the interval in which the algorithm seeks the solution. It is also possible to choose the <code>nlminb</code> algorithm. In that case, bounds for the coefficients can be set by the options <code>upper=</code> and <code>lower=</code> .
constraint	If set to TRUE, the constraint optimization algorithm is used. See <code>constrOptim</code> to learn how it works. In particular, if you choose to use it, you need to provide "ui" and "ci" in order to impose the constraint $ui\theta - ci \geq 0$ .
tol_mom	It is the tolerance for the moment condition $\sum_{t=1}^n p_t g(\theta(x_t)) = 0$ , where $p_t = \frac{1}{n} D\rho(< g_t, \lambda >)$ is the implied probability. It adds a penalty if the solution diverges from its goal.

optlam	Algorithm used to solve for the lagrange multiplier in <code>getLamb</code> . The algorithm Wu is only for type="EL". The value of optlam is ignored for "CUE" because in that case, the analytical solution exists.
data	A data.frame or a matrix with column names (Optional).
Lambdacontrol	Controls for the optimization of the vector of Lagrange multipliers used by either <code>optim</code> , <code>nlinb</code> or <code>constrOptim</code>
model, X, Y	logicals. If TRUE the corresponding components of the fit (the model frame, the model matrix, the response) are returned if g is a formula.
TypeGel	The name of the class object created by the method <code>getModel</code> . It allows developers to extend the package and create other GEL methods.
alpha	Regularization coefficient for discrete CGEL estimation (experimental). By setting alpha to any value, the model is estimated by CGEL of type specified by the option type. See Chausse (2011)
eqConst	Either a named vector (if "g" is a function), a simple vector for the nonlinear case indicating which of the $\theta_0$ is restricted, or a qx2 vector defining equality constraints of the form $\theta_i = c_i$ . See <code>gmm</code> for an example.
eqConstFullVcov	If FALSE, the constrained coefficients are assumed to be fixed and only the covariance of the unconstrained coefficients is computed. If TRUE, the covariance matrix of the full set of coefficients is computed.
onlyCoefficients	If TRUE, only the vector of coefficients and Lagrange multipliers are returned
...	More options to give to <code>optim</code> , <code>optimize</code> or <code>constrOptim</code> .

## Details

If we want to estimate a model like  $Y_t = \theta_1 + X_{2t}\theta_2 + \dots + X_k\theta_k + \epsilon_t$  using the moment conditions  $Cov(\epsilon_t H_t) = 0$ , where  $H_t$  is a vector of  $Nh$  instruments, than we can define "g" like we do for `lm`. We would have  $g = y - x_2\theta_2 - \dots - x_k\theta_k$  and the argument "x" above would become the matrix H of instruments. As for `lm`,  $Y_t$  can be a  $Ny \times 1$  vector which would imply that  $k = Nh \times Ny$ . The intercept is included by default so you do not have to add a column of ones to the matrix H. You do not need to provide the gradient in that case since in that case it is embedded in `gel`. The intercept can be removed by adding -1 to the formula. In that case, the column of ones need to be added manually to H.

If "smooth" is set to TRUE, the sample moment conditions  $\sum_{t=1}^n g(\theta, x_t)$  is replaced by:  $\sum_{t=1}^n g^k(\theta, x_t)$ , where  $g^k(\theta, x_t) = \sum_{i=-r}^r k(i)g(\theta, x_{t+i})$ , where  $r$  is a truncated parameter that depends on the bandwidth and  $k(i)$  are normalized weights so that they sum to 1.

The method solves  $\hat{\theta} = \arg \min [\arg \max_{\lambda} \frac{1}{n} \sum_{t=1}^n \rho(\langle g(\theta, x_t), \lambda \rangle) - \rho(0)]$

`evalGel` generates the object of class "gel" for a fixed vector of parameters. There is no estimation for  $\theta$ , but the optimal vector of Lagrange multipliers  $\lambda$  is computed. The objective function is then the profiled likelihood for a given  $\theta$ . It can be used to construct a confidence interval by inverting the likelihood ratio test.

**Value**

'gel' returns an object of 'class' "'gel'"

The functions 'summary' is used to obtain and print a summary of the results.

The object of class "gel" is a list containing at least the following:

coefficients	$k \times 1$ vector of parameters
residuals	the residuals, that is response minus fitted values if "g" is a formula.
fitted.values	the fitted mean values if "g" is a formula.
lambda	$q \times 1$ vector of Lagrange multipliers.
vcov_par	the covariance matrix of "coefficients"
vcov_lambda	the covariance matrix of "lambda"
pt	The implied probabilities
objective	the value of the objective function
conv_lambda	Convergence code for "lambda" (see <a href="#">getLamb</a> )
conv_mes	Convergence message for "lambda" (see <a href="#">getLamb</a> )
conv_par	Convergence code for "coefficients" (see <a href="#">optim</a> , <a href="#">optimize</a> or <a href="#">constrOptim</a> )
terms	the <a href="#">terms</a> object used when g is a formula.
call	the matched call.
y	if requested, the response used (if "g" is a formula).
x	if requested, the model matrix used if "g" is a formula or the data if "g" is a function.
model	if requested (the default), the model frame used if "g" is a formula.

## Examples

```
# First, an exemple with the fonction g()

g <- function(tet, x)
{
  n <- nrow(x)
  u <- (x[7:n] - tet[1] - tet[2]*x[6:(n-1)] - tet[3]*x[5:(n-2)])
  f <- cbind(u, u*x[4:(n-3)], u*x[3:(n-4)], u*x[2:(n-5)], u*x[1:(n-6)])
  return(f)
}

Dg <- function(tet,x)
{
  n <- nrow(x)
  xx <- cbind(rep(1, (n-6)), x[6:(n-1)], x[5:(n-2)])
  H <- cbind(rep(1, (n-6)), x[4:(n-3)], x[3:(n-4)], x[2:(n-5)], x[1:(n-6)])
  f <- -crossprod(H, xx)/(n-6)
  return(f)
}
n = 200
phi<-c(.2, .7)
thet <- 0.2
sd <- .2
set.seed(123)
x <- matrix(arima.sim(n = n, list(order = c(2, 0, 1), ar = phi, ma = thet, sd = sd)), ncol = 1)

res <- gel(g, x, c(0, .3, .6), grad = Dg)
summary(res)

# The same model but with g as a formula... much simpler in that case

y <- x[7:n]
ym1 <- x[6:(n-1)]
ym2 <- x[5:(n-2)]

H <- cbind(x[4:(n-3)], x[3:(n-4)], x[2:(n-5)], x[1:(n-6)])
g <- y ~ ym1 + ym2
x <- H
```

```

res <- gel(g, x, c(0, .3, .6))
summary(res)

# Using evalGel to create the object without estimation

res <- evalGel(g, x, res$coefficients)

```

---

getDat

*Extracting data from a formula*

---

### Description

It extract the data from a formula  $y \sim z$  with instrument  $h$  and put everything in a matrix. It helps redefine the function  $g(\theta, x)$  that is required by [gmm](#) and [gel](#).

### Usage

```
getDat(formula, h, data, error=TRUE)
```

### Arguments

formula	A formula that defines the linear model to be estimated (see details).
h	A $n \times nh$ matrix of intruments(see details).
data	A data.frame or a matrix with colnames (Optionnal).
error	If FALSE, the data is generated without giving any error message

### Details

The model to be estimated is based on the moment conditions  $\langle h, (y - z\theta) \rangle = 0$ . It adds a column of ones to  $z$  and  $h$  by default. They are removed if -1 is added to the formula. The error argument has been added for [sysGmm](#) with common coefficients because the check is only valid for equation by equation identification.

### Value

$x$ : A  $n \times l$  matrix, where  $l = ncol(y) + ncol(z) + ncol(h) + 2$  if "intercept" is TRUE and  $ncol(y) + ncol(z) + ncol(h)$  if "intercept" is FALSE.

nh: dimension of  $h$

k: dimension of  $z$

ny: dimension of  $y$

**Examples**

```

n = 500
phi<-c(.2, .7)
thet <- 0.2
sd <- .2
x <- matrix(arima.sim(n = n, list(order = c(2, 0, 1), ar = phi, ma = thet, sd = sd)), ncol = 1)
y <- x[7:n]
ym1 <- x[6:(n-1)]
ym2 <- x[5:(n-2)]
H <- cbind(x[4:(n-3)], x[3:(n-4)], x[2:(n-5)], x[1:(n-6)])

x <- getDat(y ~ ym1 + ym2, H)

```

---

getImpProb

*Implied Probabilities*

---

**Description**

It computes the implied probabilities from objects of class `gel` with additional options.

**Usage**

```

## S3 method for class 'gel'
getImpProb(object, posProb=TRUE, normalize=TRUE,
           checkConv=FALSE, ...)

```

**Arguments**

<code>object</code>	Object of class <code>gel</code> .
<code>posProb</code>	Should the implied probabilities be transformed into positive probabilities?
<code>normalize</code>	Should we normalize the probabilities so that they sum to one?
<code>checkConv</code>	Should we add the attribute convergence to check the sum of the probabilities and the weighted sum of the moment conditions?
<code>...</code>	Additional arguments to pass to other methods

**Value**

A vector of implied probabilities.

**References**

Newey, W.K. and Smith, R.J. (2004), Higher Order Properties of GMM and Generalized Empirical Likelihood Estimators. *Econometrica*, **72**, 219-255.

**Examples**

```
#####
n = 500
phi<-c(.2,.7)
thet <- 0
sd <- .2
x <- matrix(arima.sim(n=n,list(order=c(2,0,1),ar=phi,ma=thet,sd=sd)),ncol=1)
y <- x[7:n]
ym1 <- x[6:(n-1)]
ym2 <- x[5:(n-2)]

H <- cbind(x[4:(n-3)], x[3:(n-4)], x[2:(n-5)], x[1:(n-6)])
g <- y ~ ym1 + ym2
x <- H
t0 <- c(0,.5,.5)

res <- gel(g, x, t0)
pt <- getImpProb(res)
```

getLamb

*Solving for the Lagrange multipliers of Generalized Empirical Likelihood (GEL)*

**Description**

It computes the vector of Lagrange multipliers, which maximizes the GEL objective function, using an iterative Newton method.

**Usage**

```
getLamb(gt, l0, type = c("EL","ET","CUE", "ETEL", "HD","ETHD","RCUE"),
        tol_lam = 1e-7, maxiterlam = 100,
        tol_obj = 1e-7, k = 1, method = c("nllminb", "optim", "iter", "Wu"),
        control = list())
```

**Arguments**

gt	A $n \times q$ matrix with typical element $g_i(\theta, x_t)$
l0	Vector of starting values for lambda
type	"EL" for empirical likelihood, "ET" for exponential tilting, "CUE" for continuous updated estimator, and "HD" for Hellinger Distance. See details for "ETEL" and "ETHD". "RCUE" is a restricted version of "CUE" in which the probabilities are bounded below by zero. In that case, an analytical Kuhn-Tucker method is used to find the solution.
tol_lam	Tolerance for $\lambda$ between two iterations. The algorithm stops when $\ \lambda_i - \lambda_{i-1}\ $ reaches tol_lam

maxiterlam	The algorithm stops if there is no convergence after "maxiterlam" iterations.
tol_obj	Tolerance for the gradient of the objective function. The algorithm returns a non-convergence message if $\max( \text{gradient} )$ does not reach tol_obj. It helps the gel algorithm to select the right space to look for $\theta$
k	It represents the ratio $k_1/k_2$ , where $k_1 = \int_{-\infty}^{\infty} k(s)ds$ and $k_2 = \int_{-\infty}^{\infty} k(s)^2 ds$ . See Smith(2004).
method	The iterative procedure uses a Newton method for solving the FOC. It is however recommended to use optim or nlminb. If type is set to "EL" and method to "optim", constrOptim is called to prevent $\log(1 - gt'\lambda)$ from producing NA. The gradient and hessian is provided to nlminb which speed up the convergence. The latter is therefore the default value. "Wu" is for "EL" only. It uses the algorithm of Wu (2005). The value of method is ignored for "CUE" because in that case, the analytical solution exists.
control	Controls to send to optim, nlminb or constrOptim

### Details

It solves the problem  $\max_{\lambda} \frac{1}{n} \sum_{t=1}^n \rho(gt'\lambda)$ . For the type "ETEL", it is only used by gel. In that case  $\lambda$  is obtained by maximizing  $\frac{1}{n} \sum_{t=1}^n \rho(gt'\lambda)$ , using  $\rho(v) = -\exp v$  (so ET) and  $\theta$  by minimizing the same equation but with  $\rho(v) = \log(1 - v)$ . To avoid NA's, constrOptim is used with the restriction  $\lambda'g_t < 1$ . The type "ETHD" is experimental and proposed by Antoine-Dovonon (2015). The paper is not yet available.

### Value

lambda: A  $q \times 1$  vector of Lagrange multipliers which solve the system of equations given above.  
conv: Details on the type of convergence.

### Examples

```
g <- function(tet,x)
{
  n <- nrow(x)
  u <- (x[7:n] - tet[1] - tet[2]*x[6:(n-1)] - tet[3]*x[5:(n-2)])
  f <- cbind(u, u*x[4:(n-3)], u*x[3:(n-4)], u*x[2:(n-5)], u*x[1:(n-6)])
  return(f)
}
n = 500
phi<-c(.2, .7)
thet <- 0.2
```

```
sd <- .2
x <- matrix(arima.sim(n = n, list(order = c(2, 0, 1), ar = phi, ma = thet, sd = sd)), ncol = 1)
gt <- g(c(0,phi),x)
getLamb(gt, type = "EL",method="optim")
```

---

getModel

---

*Method for setting the properties of a model*

---

## Description

It collects what is needed by the method `momentEstim` (see details).

## Usage

```
## S3 method for class 'baseGmm'
getModel(object, ...)
## S3 method for class 'sysGmm'
getModel(object, ...)
## S3 method for class 'baseGel'
getModel(object, ...)
## S3 method for class 'constGel'
getModel(object, ...)
## S3 method for class 'constGel'
getModel(object, ...)
## S3 method for class 'tsls'
getModel(object, ...)
## S3 method for class 'ateGel'
getModel(object, ...)
```

## Arguments

<code>object</code>	An object of class <code>baseGmm</code>
<code>...</code>	Other arguments when <code>getModel</code> is applied to another class object

## Value

It returns an object of the right class which determines how the method `momentEstim` will treat it. For example, if `g` is a formula and `type` is set to "cue", it creates an object of class `baseGmm.cue.formula`. In this case, `momentEstim`, applied to this object, computes the continuously updated GMM of a linear model. It allows more flexibility this way. For example, it could be easy to add a GMM method which is robust in presence of weak identification simply by creating a new class of model and the associated `momentEstim` method.

gmm

*Generalized method of moment estimation***Description**

Function to estimate a vector of parameters based on moment conditions using the GMM method of Hansen(82).

**Usage**

```
gmm(g,x,t0=NULL,gradv=NULL, type=c("twoStep","cue","iterative"),
    wmatrix = c("optimal","ident"), vcov=c("HAC","MDS","iid","TrueFixed"),
    kernel=c("Quadratic Spectral","Truncated", "Bartlett", "Parzen", "Tukey-Hanning"),
    crit=10e-7,bw = bwAndrews, prewhite = 1, ar.method = "ols", approx="AR(1)",
    tol = 1e-7, itermax=100,optfct=c("optim","optimize","nlnmb", "constrOptim"),
    model=TRUE, X=FALSE, Y=FALSE, TypeGmm = "baseGmm", centeredVcov = TRUE,
    weightsMatrix = NULL, traceIter = FALSE, data, eqConst = NULL,
    eqConstFullVcov = FALSE, mustar = NULL, onlyCoefficients=FALSE, ...)
evalGmm(g, x, t0, tetw=NULL, gradv=NULL, wmatrix = c("optimal","ident"),
    vcov=c("HAC","iid","TrueFixed"), kernel=c("Quadratic Spectral","Truncated",
    "Bartlett", "Parzen", "Tukey-Hanning"),crit=10e-7,bw = bwAndrews,
    prewhite = FALSE, ar.method = "ols", approx="AR(1)",tol = 1e-7,
    model=TRUE, X=FALSE, Y=FALSE, centeredVcov = TRUE, weightsMatrix = NULL,
    data, mustar = NULL)
gmmWithConst(obj, which, value)
```

**Arguments**

g	A function of the form $g(\theta, x)$ and which returns a $n \times q$ matrix with typical element $g_i(\theta, x_t)$ for $i = 1, \dots, q$ and $t = 1, \dots, n$ . This matrix is then used to build the $q$ sample moment conditions. It can also be a formula if the model is linear (see details below).
x	The matrix or vector of data from which the function $g(\theta, x)$ is computed. If "g" is a formula, it is an $n \times Nh$ matrix of instruments or a formula (see details below).
t0	A $k \times 1$ vector of starting values. It is required only when "g" is a function because only then a numerical algorithm is used to minimize the objective function. If the dimension of $\theta$ is one, see the argument "optfct".
tetw	A $k \times 1$ vector to compute the weighting matrix.
gradv	A function of the form $G(\theta, x)$ which returns a $q \times k$ matrix of derivatives of $\bar{g}(\theta)$ with respect to $\theta$ . By default, the numerical algorithm <code>numericDeriv</code> is used. It is of course strongly suggested to provide this function when it is possible. This gradient is used to compute the asymptotic covariance matrix of $\hat{\theta}$ and to obtain the analytical gradient of the objective function if the method is set to "CG" or "BFGS" in <code>optim</code> and if "type" is not set to "cue". If "g" is a formula, the gradient is not required (see the details below).

type	The GMM method: "twostep" is the two step GMM proposed by Hansen(1982) and the "cue" and "iterative" are respectively the continuous updated and the iterative GMM proposed by Hansen, Eaton et Yaron (1996)
wmatrix	Which weighting matrix should be used in the objective function. By default, it is the inverse of the covariance matrix of $g(\theta, x)$ . The other choice is the identity matrix which is usually used to obtain a first step estimate of $\theta$
vcov	Assumption on the properties of the random vector $x$ . By default, $x$ is a weakly dependant process. The "iid" option will avoid using the HAC matrix which will accelerate the estimation if one is ready to make that assumption. The option "TrueFixed" is used only when the matrix of weights is provided and it is the optimal one.
kernel	type of kernel used to compute the covariance matrix of the vector of sample moment conditions (see <a href="#">kernHAC</a> for more details)
crit	The stopping rule for the iterative GMM. It can be reduce to increase the precision.
bw	The method to compute the bandwidth parameter in the HAC weighting matrix. The default is <code>link{bwAndrews}</code> (as proposed in Andrews (1991)), which minimizes the MSE of the weighting matrix. Alternatives are <code>link{bwWilhelm}</code> (as proposed in Wilhelm (2015)), which minimizes the mean-square error (MSE) of the resulting GMM estimator, and <code>link{bwNeweyWest}</code> (as proposed in Newey-West(1994)).
prewhite	logical or integer. Should the estimating functions be prewhitened? If TRUE or greater than 0 a VAR model of order <code>as.integer(prewhite)</code> is fitted via <code>ar</code> with method "ols" and <code>demean = FALSE</code> .
ar.method	character. The method argument passed to <code>ar</code> for prewhitening.
approx	A character specifying the approximation method if the bandwidth has to be chosen by <code>bwAndrews</code> .
tol	Weights that exceed <code>tol</code> are used for computing the covariance matrix, all other weights are treated as 0.
itermax	The maximum number of iterations for the iterative GMM. It is unlikely that the algorithm does not converge but we keep it as a safety.
optfct	Only when the dimension of $\theta$ is 1, you can choose between the algorithm <code>optim</code> or <code>optimize</code> . In that case, the former is unreliable. If <code>optimize</code> is chosen, "t0" must be $1 \times 2$ which represents the interval in which the algorithm seeks the solution. It is also possible to choose the <code>nlminb</code> algorithm. In that case, boundaries for the coefficients can be set by the options <code>upper=</code> and <code>lower=</code> . The <code>constrOptim</code> is only available for nonlinear models for now. The standard errors may have to be corrected if the estimates reach the boundary set by <code>ui</code> and <code>ci</code> .
model, X, Y	logical. If TRUE the corresponding components of the fit (the model frame, the model matrix, the response) are returned if <code>g</code> is a formula.
TypeGmm	The name of the class object created by the method <code>getModel</code> . It allows developers to extend the package and create other GMM methods.
centeredVcov	Should the moment function be centered when computing its covariance matrix. Doing so may improve inference.

weightsMatrix	It allows users to provide gmm with a fixed weighting matrix. This matrix must be $q \times q$ , symmetric and strictly positive definite. When provided, the type option becomes irrelevant.
traceIter	Tracing information for GMM of type "iter"
data	A data.frame or a matrix with column names (Optional).
eqConst	Either a named vector (if "g" is a function), a simple vector for the nonlinear case indicating which of the $\theta_0$ is restricted, or a qx2 vector defining equality constraints of the form $\theta_i = c_i$ . See below for an example.
which, value	The equality constraint is of the form which=value. "which" can be a vector of type characters with the names of the coefficients being constrained, or a vector of type numeric with the position of the coefficient in the whole vector.
obj	Object of class "gmm"
eqConstFullVcov	If FALSE, the constrained coefficients are assumed to be fixed and only the covariance of the unconstrained coefficients is computed. If TRUE, the covariance matrix of the full set of coefficients is computed.
mustar	If not null, it must be a vector with the number of elements being equal to the number of moment conditions. In that case, the vector is subtracted from the sample moment vector before minimizing the objective function. It is useful to do a bootstrap procedure.
onlyCoefficients	If set to TRUE, the function only returns the coefficient estimates. It may be of interest when the standard errors are not needed
...	More options to give to <a href="#">optim</a> .

## Details

If we want to estimate a model like  $Y_t = \theta_1 + X_{2t}\theta_2 + \dots + X_k\theta_k + \epsilon_t$  using the moment conditions  $Cov(\epsilon_t H_t) = 0$ , where  $H_t$  is a vector of  $Nh$  instruments, than we can define "g" like we do for [lm](#). We would have  $g = y - x_2 - x_3 - \dots - x_k$  and the argument "x" above would become the matrix H of instruments. As for [lm](#),  $Y_t$  can be a  $Ny \times 1$  vector which would imply that  $k = Nh \times Ny$ . The intercept is included by default so you do not have to add a column of ones to the matrix H. You do not need to provide the gradient in that case since in that case it is embedded in [gmm](#). The intercept can be removed by adding -1 to the formula. In that case, the column of ones need to be added manually to H. It is also possible to express "x" as a formula. For example, if the instruments are  $\{1, z_1, z_2, z_3\}$ , we can set "x" to  $\tilde{z}_1 + z_2 + z_3$ . By default, a column of ones is added. To remove it, set "x" to  $\tilde{z}_1 + z_2 + z_3 - 1$ .

The following explains the last example bellow. Thanks to Dieter Rozenich, a student from the Vienna University of Economics and Business Administration. He suggested that it would help to understand the implementation of the Jacobian.

For the two parameters of a normal distribution  $(\mu, \sigma)$  we have the following three moment conditions:

$$\begin{aligned} m_1 &= \mu - x_i \\ m_2 &= \sigma^2 - (x_i - \mu)^2 \\ m_3 &= x_i^3 - \mu(\mu^2 + 3\sigma^2) \end{aligned}$$

$m_1, m_2$  can be directly obtained by the definition of  $(\mu, \sigma)$ . The third moment condition comes from the third derivative of the moment generating function (MGF)

$$M_X(t) = \exp\left(\mu t + \frac{\sigma^2 t^2}{2}\right)$$

evaluated at  $(t = 0)$ .

Note that we have more equations (3) than unknown parameters (2).

The Jacobian of these two conditions is (it should be an array but I can't make it work):

$$\begin{array}{cc} 1 & 0 \\ -2\mu + 2x & 2\sigma \\ -3\mu^2 - 3\sigma^2 & -6\mu\sigma \end{array}$$

`gmmWithConst()` re-estimates an unrestricted model by adding an equality constraint. `evalGmm()` creates an object of class "gmm" for a given parameter vector. If no vector "tetw" is provided and the weighting matrix needs to be computed, "t0" is used.,

## Value

'gmm' returns an object of 'class' "gmm"

The functions 'summary' is used to obtain and print a summary of the results. It also compute the J-test of overidentifying restriction

The object of class "gmm" is a list containing at least:

coefficients	$k \times 1$ vector of coefficients
residuals	the residuals, that is response minus fitted values if "g" is a formula.
fitted.values	the fitted mean values if "g" is a formula.
vcov	the covariance matrix of the coefficients
objective	the value of the objective function $\ var(\bar{g})^{-1/2}\bar{g}\ ^2$
terms	the <code>terms</code> object used when g is a formula.
call	the matched call.
y	if requested, the response used (if "g" is a formula).
x	if requested, the model matrix used if "g" is a formula or the data if "g" is a function.
model	if requested (the default), the model frame used if "g" is a formula.
algoInfo	Information produced by either <code>optim</code> or <code>nlminb</code> related to the convergence if "g" is a function. It is printed by the <code>summary.gmm</code> method.

## Examples

```
## CAPM test with GMM
data(Finance)
r <- Finance[1:300, 1:10]
rm <- Finance[1:300, "rm"]
rf <- Finance[1:300, "rf"]

z <- as.matrix(r-rf)
t <- nrow(z)
zm <- rm-rf
h <- matrix(zm, t, 1)
res <- gmm(z ~ zm, x = h)
summary(res)

## linear tests can be performed using linearHypothesis from the car package
## The CAPM can be tested as follows:

library(car)
linearHypothesis(res,cbind(diag(10),matrix(0,10,10)),rep(0,10))

# The CAPM of Black
g <- function(theta, x) {
e <- x[,2:11] - theta[1] - (x[,1] - theta[1]) %*% matrix(theta[2:11], 1, 10)
gmat <- cbind(e, e*c(x[,1]))
return(gmat) }

x <- as.matrix(cbind(rm, r))
res_black <- gmm(g, x = x, t0 = rep(0, 11))

summary(res_black)$coefficients
```

```

## APT test with Fama-French factors and GMM

f1 <- zm
f2 <- Finance[1:300, "hml"]
f3 <- Finance[1:300, "smb"]
h <- cbind(f1, f2, f3)
res2 <- gmm(z ~ f1 + f2 + f3, x = h)
coef(res2)
summary(res2)$coefficients

## Same result with x defined as a formula:

res2 <- gmm(z ~ f1 + f2 + f3, ~ f1 + f2 + f3)
coef(res2)

## The following example has been provided by Dieter Rozenich (see details).
# It generates normal random numbers and uses the GMM to estimate
# mean and sd.
#-----
# Random numbers of a normal distribution
# First we generate normally distributed random numbers and compute the two parameters:
n <- 1000
x <- rnorm(n, mean = 4, sd = 2)
# Implementing the 3 moment conditions
g <- function(tet, x)
{
  m1 <- (tet[1] - x)
  m2 <- (tet[2]^2 - (x - tet[1])^2)
  m3 <- x^3 - tet[1]*(tet[1]^2 + 3*tet[2]^2)
  f <- cbind(m1, m2, m3)
  return(f)
}
# Implementing the jacobian
Dg <- function(tet, x)
{
  jacobian <- matrix(c( 1, 2*(-tet[1]+mean(x)), -3*tet[1]^2-3*tet[2]^2, 0, 2*tet[2],
-6*tet[1]*tet[2]), nrow=3, ncol=2)
  return(jacobian)
}
# Now we want to estimate the two parameters using the GMM.
gmm(g, x, c(0, 0), grad = Dg)

# Two-stage-least-squares (2SLS), or IV with iid errors.
# The model is:
#  $Y(t) = b[0] + b[1]C(t) + b[2]Y(t-1) + e(t)$ 
#  $e(t)$  is an MA(1)
# The instruments are  $Z(t) = \{1 \ C(t) \ y(t-2) \ y(t-3) \ y(t-4)\}$ 

getdat <- function(n) {
  e <- arima.sim(n,model=list(ma=.9))
  C <- runif(n,0,5)
  Y <- rep(0,n)

```

```

Y[1] = 1 + 2*C[1] + e[1]
for (i in 2:n){
Y[i] = 1 + 2*C[i] + 0.9*Y[i-1] + e[i]
}
Yt <- Y[5:n]
X <- cbind(1,C[5:n],Y[4:(n-1)])
Z <- cbind(1,C[5:n],Y[3:(n-2)],Y[2:(n-3)],Y[1:(n-4)])
return(list(Y=Yt,X=X,Z=Z))
}

d <- getdat(5000)
res4 <- gmm(d$Y~d$X-1,~d$Z-1,vcov="iid")
res4

### Examples with equality constraint
#####

# Random numbers of a normal distribution

## Not run:
# The following works but produces warning message because the dimension of coef is 1
# Brent should be used

# without named vector
# Method Brent is used because the problem is now one-dimensional
gmm(g, x, c(4, 0), grad = Dg, eqConst=1, method="Brent", lower=-10,upper=10)
# with named vector
gmm(g, x, c(mu=4, sig=2), grad = Dg, eqConst="sig", method="Brent", lower=-10,upper=10)

## End(Not run)

gmm(g, x, c(4, 0), grad = Dg, eqConst=1,method="Brent",lower=0,upper=6)

                 t0=res2$coefficients, tetw=res2$coefficients)
summary(res2_2)
```

---

Growth

*Growth Data*

---

### Description

Panel of Macroeconomic data for 125 countries from 1960 to 1985 constructed by Summers and Heston (1991))

### Usage

```
data(Growth)
```

### Format

A data frame containing 9 vectors.

**Country\_ID** Country identification number

**COM** 1 if the country is in a communist regime, 0 otherwise

**OPEC** 1 if the country is part of the OPEC, 0 otherwise

**Year** Year

**GDP** Per capita GDP (in thousands) in 1985 U.S. dollars.

**LagGDP** GDP of the previous period

**SavRate** Saving rate measured as the ratio of real investment to real GDP

**LagSavRate** SavRate of the previous period

**Country** Country names

**Pop** Population in thousands

**LagPop** Population of the previous period

**Source**

<http://fhayashi.fc2web.com/datasets.htm>

---

KTest

*Compute the K statistics of Kleibergen*

---

**Description**

The test is proposed by Kleibergen (2005). It is robust to weak identification.

**Usage**

```
KTest(obj, theta0 = NULL, alphaK = 0.04, alphaJ = 0.01)
## S3 method for class 'gmmTests'
print(x, digits = 5, ...)
```

**Arguments**

obj	Object of class "gmm" returned by <a href="#">gmm</a>
theta0	The null hypothesis being tested. See details.
alphaK, alphaJ	The size of the J and K tests when combining the two. The overall size is alphaK+alphaJ.
x	An object of class gmmTests returned by KTest
digits	The number of digits to be printed
...	Other arguments when print is applied to another class object

**Details**

The function produces the J-test and K-statistics which are robust to weak identification. The test is either  $H_0 : \theta = \theta_0$ , in which case theta0 must be provided, or  $\beta = \beta_0$ , where  $\theta = (\alpha', \beta)'$ , and  $\alpha$  is assumed to be identified. In the latter case, theta0 is NULL and obj is a restricted estimation in which  $\beta$  is fixed to  $\beta_0$ . See [gmm](#) and the option "eqConst" for more details.

**Value**

Tests and p-values

**References**

Keibergen, F. (2005), Testing Parameters in GMM without assuming that they are identified. *Econometrica*, **73**, 1103-1123,

**Examples**

```

library(mvtnorm)
sig <- matrix(c(1,.5,.5,1),2,2)
n <- 400
e <- rmvnorm(n,sigma=sig)
x4 <- rnorm(n)
w <- exp(-x4^2) + e[,1]
y <- 0.1*w + e[,2]
h <- cbind(x4, x4^2, x4^3, x4^6)
g3 <- y~w
res <- gmm(g3,h)

# Testing the whole vector:

KTest(res,theta0=c(0,.1))

# Testing a subset of the vector (See \code{\link{gmm}})

res2 <- gmm(g3, h, eqConst=matrix(c(2,.1),1,2))
res2
KTest(res2)

```

---

marginal

*Marginal effects Summary*

---

**Description**

It produces the summary table of marginal effects for GLM estimation with GEL. Only implemented for ATEgel.

**Usage**

```

## S3 method for class 'ategel'
marginal(object, ...)

```

**Arguments**

object	An object of class <code>ategel</code> returned by the function <code>ATEgel</code>
...	Other arguments for other methods

**Value**

It returns a matrix with the marginal effects, the standard errors based on the Delta method when the link is nonlinear, the t-ratios, and the pvalues.

```

---

momentEstim

*Method for estimating models based on moment conditions*

---

## Description

It estimates a model which is characterized by the method getModel (see details).

## Usage

```
## S3 method for class 'baseGmm.twoStep'
momentEstim(object, ...)
## S3 method for class 'baseGmm.twoStep.formula'
momentEstim(object, ...)
## S3 method for class 'sysGmm.twoStep.formula'
momentEstim(object, ...)
## S3 method for class 'tsls.twoStep.formula'
```

```

momentEstim(object, ...)
## S3 method for class 'baseGmm.iterative.formula'
momentEstim(object, ...)
## S3 method for class 'baseGmm.iterative'
momentEstim(object, ...)
## S3 method for class 'baseGmm.cue.formula'
momentEstim(object, ...)
## S3 method for class 'baseGmm.cue'
momentEstim(object, ...)
## S3 method for class 'baseGmm.eval'
momentEstim(object, ...)
## S3 method for class 'baseGel.mod'
momentEstim(object, ...)
## S3 method for class 'baseGel.modFormula'
momentEstim(object, ...)
## S3 method for class 'baseGel.eval'
momentEstim(object, ...)

```

### Arguments

object            An object created by the method getModel  
 ...                Other arguments when momentEstim is applied to an other class object

### Value

It returns an object of class determined by the argument "TypeGMM" of `gmm`. By default, it is of class `baseGmm.res`. It estimates the model and organize the results that will be finalized by the method `FinRes`. More methods can be created in order to use other GMM methods not yet included in the package.

 nsw

*Lalonde subsample of the National Supported Work Demonstration Data (NSW)*

---

### Description

This data was collected to evaluate the National Supported Work (NSW) Demonstration project in Lalonde (1986).

**Usage**

```
data(nsw)
```

**Format**

A data frame containing 9 variables.

**treat** Treatment assignment

**age** Age

**ed** Years of Education

**black** 1 if Black, 0 otherwise

**hisp** 1 if Hispanic 0 otherwise

**married** 1 if married 0 otherwise

**nodeg** 1 if no college degree 0 otherwise

**re75** 1975 earnings

**re78** 1978 earnings

**Details**

The dataset was obtained from the ATE package (see reference).

Asad Haris and Gary Chan (2015). ATE: Inference for Average Treatment Effects using Covariate Balancing. R package version 0.2.0. <https://CRAN.R-project.org/package=ATE>

**Description**

It is a plot method for *gel* or *gmm* objects.

**Usage**

```
## S3 method for class 'gel'
plot(x, which = c(1L:4),
     main = list("Residuals vs Fitted values", "Normal Q-Q",
                "Response variable and fitted values", "Implied probabilities"),
     panel = if(add.smooth) panel.smooth else points,
     ask = prod(par("mfcol")) < length(which) && dev.interactive(), ...,
     add.smooth = getOption("add.smooth"))

## S3 method for class 'gmm'
plot(x, which = c(1L:3),
     main = list("Residuals vs Fitted values", "Normal Q-Q",
                "Response variable and fitted values"),
     panel = if(add.smooth) panel.smooth else points,
     ask = prod(par("mfcol")) < length(which) && dev.interactive(), ...,
     add.smooth = getOption("add.smooth"))
```

**Arguments**

<code>x</code>	<i>gel</i> or <i>gmm</i> object, typically result of <a href="#">gel</a> or <a href="#">gmm</a> .
<code>which</code>	if a subset of the plots is required, specify a subset of the numbers 1:4 for <i>gel</i> or 1:3 for <i>gmm</i> .
<code>main</code>	Vector of titles for each plot.
<code>panel</code>	panel function. The useful alternative to <a href="#">points</a> , <a href="#">panel.smooth</a> can be chosen by <code>add.smooth = TRUE</code> .
<code>ask</code>	logical; if TRUE, the user is <i>asked</i> before each plot, see <a href="#">par(ask=.)</a> .
<code>...</code>	other parameters to be passed through to plotting functions.
<code>add.smooth</code>	logical indicating if a smoother should be added to most plots; see also <a href="#">panel</a> above.

**Details**

It is a beta version of a plot method for *gel* objects. It is a modified version of `plot.lm`. For now, it is available only for linear models expressed as a formula. Any suggestions are welcome regarding plots or options to include. The first two plots are the same as the ones provided by `plot.lm`, the third is the dependant variable  $y$  with its mean  $\hat{y}$  (the fitted values) and the last plots the implied probabilities with the empirical density  $1/T$ .

**Examples**

```

# GEL #
n = 500
phi<-c(.2,.7)
thet <- 0
sd <- .2
x <- matrix(arima.sim(n = n,list(order = c(2,0,1), ar = phi, ma = thet, sd = sd)), ncol = 1)
y <- x[7:n]
ym1 <- x[6:(n-1)]
ym2 <- x[5:(n-2)]

H <- cbind(x[4:(n-3)], x[3:(n-4)], x[2:(n-5)], x[1:(n-6)])
g <- y ~ ym1 + ym2
x <- H
t0 <- c(0,.5,.5)

res <- gel(g, x, t0)

plot(res, which = 3)
plot(res, which = 4)

# GMM #

res <- gmm(g, x)
plot(res, which = 3)

```

---

print

---

*Printing a gmm or gel object*

---

**Description**

It is a printing method for gmm or gel objects.

**Usage**

```

## S3 method for class 'gmm'
print(x, digits = 5, ...)
## S3 method for class 'gel'
print(x, digits = 5, ...)
## S3 method for class 'sysGmm'
print(x, digits = 5, ...)

```

**Arguments**

x	An object of class gmm or gel returned by the function <code>gmm</code> or <code>gel</code>
digits	The number of digits to be printed
...	Other arguments when print is applied to an other class object

**Value**

It prints some results from the estimation like the coefficients and the value of the objective function.

**Examples**

```
# GMM #

n = 500
phi<-c(.2,.7)
thet <- 0
sd <- .2
x <- matrix(arima.sim(n = n, list(order = c(2,0,1), ar = phi, ma = thet, sd = sd)), ncol = 1)
y <- x[7:n]
ym1 <- x[6:(n-1)]
ym2 <- x[5:(n-2)]

H <- cbind(x[4:(n-3)], x[3:(n-4)], x[2:(n-5)], x[1:(n-6)])
g <- y ~ ym1 + ym2
x <- H

res <- gmm(g, x)
print(res)

# GEL #

t0 <- c(0,.5,.5)
res <- gel(g,x,t0)
print(res)
```

---

residuals

*Residuals of GEL or GMM*

---

**Description**

Method to extract the residuals of the model estimated by `gmm` or `gel`.

**Usage**

```
## S3 method for class 'gel'
residuals(object, ...)
## S3 method for class 'gmm'
residuals(object, ...)
```

**Arguments**

`object` An object of class `gmm` or `gel` returned by the function `gmm` or `gel`  
`...` Other arguments when `residuals` is applied to an other classe object

**Value**

It returns the matrix of residuals  $(y - \hat{y})$  in  $g=y\sim x$  as it is done by `residuals.lm`.

**Examples**

```
# GEL can deal with endogeneity problems

n = 200
phi<-c(.2,.7)
thet <- 0.2
sd <- .2
set.seed(123)
x <- matrix(arima.sim(n = n, list(order = c(2,0,1), ar = phi, ma = thet, sd = sd)), ncol = 1)

y <- x[7:n]
ym1 <- x[6:(n-1)]
ym2 <- x[5:(n-2)]
H <- cbind(x[4:(n-3)], x[3:(n-4)], x[2:(n-5)], x[1:(n-6)])
g <- y ~ ym1 + ym2
x <- H

res <- gel(g, x, c(0,.3,.6))
e <- residuals(res)
plot(e, type = 'l', main = "Residuals from an ARMA fit using GEL")

# GMM is like GLS for linear models without endogeneity problems

set.seed(345)
n = 200
phi<-c(.2,.7)
thet <- 0
sd <- .2
x <- matrix(arima.sim(n = n, list(order = c(2,0,1), ar = phi, ma = thet, sd = sd)), ncol = 1)
y <- 10 + 5*rnorm(n) + x

res <- gmm(y ~ x, x)
plot(x, residuals(res), main = "Residuals of an estimated model with GMM")
```

**Description**

It applies the required kernel smoothing to the moment function in order for the GEL estimator to be valid. It is used by the `gel` function.

**Usage**

```
smoothG(x, bw = bwAndrews, prewhite = 1, ar.method = "ols", weights = weightsAndrews,
kernel = c("Bartlett", "Parzen", "Truncated", "Tukey-Hanning"),
approx = c("AR(1)", "ARMA(1,1)"), tol = 1e-7)
```

**Arguments**

x	a $n \times q$ matrix of time series, where n is the sample size.
bw	The method to compute the bandwidth parameter. By default, it uses the bandwidth proposed by Andrews(1991). As an alternative, we can choose bw=bwNeweyWest (without "") which is proposed by Newey-West(1996).
prewhite	logical or integer. Should the estimating functions be prewhitened? If TRUE or greater than 0 a VAR model of order as.integer(prewhite) is fitted via ar with method "ols" and demean = FALSE.
ar.method	character. The method argument passed to ar for prewhitening.
weights	The smoothing weights can be computed by weightsAndrews or it can be provided manually. If provided, it has to be a $r \times 1$ vector (see details).
approx	a character specifying the approximation method if the bandwidth has to be chosen by bwAndrews.
tol	numeric. Weights that exceed tol are used for computing the covariance matrix, all other weights are treated as 0.
kernel	The choice of kernel

**Details**

The sample moment conditions  $\sum_{t=1}^n g(\theta, x_t)$  is replaced by:  $\sum_{t=1}^n g^k(\theta, x_t) = \sum_{i=-r}^r k(i)g(\theta, x_{t+i})$ , where  $r$  is a truncated parameter that depends on the bandwidth and  $k(i)$  are normalized weights so that they sum to 1.

If the vector of weights is provided, it gives only one side weights. For example, if you provide the vector (1,.5,.25),  $k(i)$  will become  $(.25, .5, 1, .5, .25)/(.25 + .5 + 1 + .5 + .25) = (.1, .2, .4, .2, .1)$

**Value**

smoothx: A  $q \times q$  matrix containing an estimator of the asymptotic variance of  $\sqrt{n}\bar{x}$ , where  $\bar{x}$  is  $q \times 1$  vector with typical element  $\bar{x}_i = \frac{1}{n} \sum_{j=1}^n x_{ji}$ . This function is called by gel but can also be used by itself.

kern\_weights: Vector of weights used for the smoothing.

### Examples

```
g <- function(tet, x)
{
  n <- nrow(x)
  u <- (x[7:n] - tet[1] - tet[2]*x[6:(n-1)] - tet[3]*x[5:(n-2)])
  f <- cbind(u, u*x[4:(n-3)], u*x[3:(n-4)], u*x[2:(n-5)], u*x[1:(n-6)])
  return(f)
}
n = 500
phi<-c(.2, .7)
thet <- 0.2
sd <- .2
x <- matrix(arima.sim(n = n, list(order = c(2, 0, 1), ar = phi, ma = thet, sd = sd)), ncol = 1)
gt <- g(c(0, phi), x)
sgt <- smoothG(gt)$smoothx
plot(gt[,1])
lines(sgt[,1])
```

---

specTest

*Compute tests of specification*

---

### Description

Generic function for testing the specification of estimated models. It computes the J-test from gmm objects and J-test, LR-test and LM-test from gel objects.

### Usage

```
## S3 method for class 'gmm'
specTest(x, ...)
## S3 method for class 'gel'
specTest(x, ...)
## S3 method for class 'specTest'
print(x, digits = 5, ...)
specTest(x, ...)
```

### Arguments

x	A fitted model object.
digits	The number of digits to be printed.
...	Arguments passed to methods.

### Value

Tests and p-values

summary

*Method for object of class gmm or gel*

---

## Description

It presents the results from the gmm or gel estimation in the same fashion as summary does for the lm class objects for example. It also compute the tests for overidentifying restrictions.

## Usage

```
## S3 method for class 'gmm'
summary(object, ...)
## S3 method for class 'sysGmm'
summary(object, ...)
## S3 method for class 'gel'
summary(object, ...)
```

```
## S3 method for class 'ategel'
summary(object, robToMiss = TRUE, ...)
## S3 method for class 'tsls'
summary(object, vcov = NULL, ...)
## S3 method for class 'summary.gmm'
print(x, digits = 5, ...)
## S3 method for class 'summary.sysGmm'
print(x, digits = 5, ...)
## S3 method for class 'summary.gel'
print(x, digits = 5, ...)
## S3 method for class 'summary.tsls'
print(x, digits = 5, ...)
```

### Arguments

object	An object of class <code>gmm</code> or <code>gel</code> returned by the function <code>gmm</code> or <code>gel</code>
x	An object of class <code>summary.gmm</code> or <code>summary.gel</code> returned by the function <code>summary.gmm</code> or <code>summary.gel</code>
digits	The number of digits to be printed
vcov	An alternative covariance matrix computed with <code>vcov.tsls</code>
robToMiss	If TRUE, it computes the robust to misspecification covariance matrix
...	Other arguments when <code>summary</code> is applied to another class object

### Value

It returns a list with the parameter estimates and their standard deviations, t-stat and p-values. It also returns the J-test and p-value for the null hypothesis that  $E(g(\theta, X)) = 0$

summary(res)

```

---

sysGmm

*Generalized method of moment estimation for system of equations*

---

## Description

Functions to estimate a system of equations based on GMM.

## Usage

```

sysGmm(g, h, wmatrix = c("optimal","ident"),
vcov=c("MDS", "HAC", "CondHom", "TrueFixed"),
kernel=c("Quadratic Spectral","Truncated", "Bartlett", "Parzen", "Tukey-Hanning"),
crit=10e-7,bw = bwAndrews, prewhite = FALSE, ar.method = "ols", approx="AR(1)",
tol = 1e-7, model=TRUE, X=FALSE, Y=FALSE, centeredVcov = TRUE,
weightsMatrix = NULL, data, crossEquConst = NULL, commonCoef = FALSE)
five(g, h, commonCoef = FALSE, data = NULL)
threeSLS(g, h, commonCoef = FALSE, data = NULL)
sur(g, commonCoef = FALSE, data = NULL)
randEffect(g, data = NULL)

```

**Arguments**

<code>g</code>	A possibly named list of formulas
<code>h</code>	A formula if the same instruments are used in each equation or a list of formulas.
<code>wmatrix</code>	Which weighting matrix should be used in the objective function. By default, it is the inverse of the covariance matrix of $g(\theta, x)$ . The other choice is the identity matrix.
<code>vcov</code>	Assumption on the properties of the moment vector. By default, it is a martingale difference sequence. "HAC" is for weakly dependent processes and "Cond-Hom" implies conditional homoscedasticity. The option "TrueFixed" is used only when the matrix of weights is provided and it is the optimal one.
<code>kernel</code>	type of kernel used to compute the covariance matrix of the vector of sample moment conditions (see <a href="#">kernHAC</a> for more details)
<code>crit</code>	The stopping rule for the iterative GMM. It can be reduce to increase the precision.
<code>bw</code>	The method to compute the bandwidth parameter. By default it is <a href="#">bwAndrews</a> which is proposed by Andrews (1991). The alternative is <a href="#">bwNeweyWest</a> of Newey-West(1994).
<code>prewhite</code>	logical or integer. Should the estimating functions be prewhitened? If TRUE or greater than 0 a VAR model of order <code>as.integer(prewhite)</code> is fitted via <code>ar</code> with method "ols" and <code>demean = FALSE</code> .
<code>ar.method</code>	character. The method argument passed to <a href="#">ar</a> for prewhitening.
<code>approx</code>	A character specifying the approximation method if the bandwidth has to be chosen by <a href="#">bwAndrews</a> .
<code>tol</code>	Weights that exceed <code>tol</code> are used for computing the covariance matrix, all other weights are treated as 0.
<code>model, X, Y</code>	logical. If TRUE the corresponding components of the fit (the model frame, the model matrix, the response) are returned if <code>g</code> is a formula.
<code>centeredVcov</code>	Should the moment function be centered when computing its covariance matrix. Doing so may improve inference.
<code>weightsMatrix</code>	It allows users to provide <code>gmm</code> with a fixed weighting matrix. This matrix must be $q \times q$ , symmetric and strictly positive definite. When provided, the <code>type</code> option becomes irrelevant.
<code>data</code>	A <code>data.frame</code> or a matrix with column names (Optional).
<code>commonCoef</code>	If true, coefficients across equations are the same
<code>crossEquConst</code>	Only used if the number of regressors are the same in each equation. It is a vector which indicates which coefficient are constant across equations. The order is 1 for Intercept and 2 to <code>k</code> as it is formulated in the formulas <code>g</code> . Setting it to <code>1:k</code> is equivalent to setting <code>commonCoef</code> to TRUE.

**Details**

This set of functions implement the estimation of system of equations as presented in Hayashi (2000)

**Value**

'sysGmm' returns an object of 'class' "'sysGmm'"

The functions 'summary' is used to obtain and print a summary of the results. It also compute the J-test of overidentifying restriction

The object of class "sysGmm" is a list containing at least:

coefficients	list of vectors of coefficients for each equation
residuals	list of the residuals for each equation.
fitted.values	list of the fitted values for each equation.
vcov	the covariance matrix of the stacked coefficients
objective	the value of the objective function $\ var(\bar{g})^{-1/2}\bar{g}\ ^2$
terms	The list of <a href="#">terms</a> objects for each equation
call	the matched call.
y	If requested, a list of response variables.
x	if requested, a list of the model matrices.
model	if requested (the default), a list of the model frames.

**Examples**

```
data(wage)

eq1 <- LW~S+IQ+EXPR
eq2 <- LW80~S80+IQ+EXPR80
g2 <- list(Wage69=eq1, WAGE80=eq2)
h2 <- list(~S+EXPR+MED+KWW, ~S80+EXPR80+MED+KWW)

res <- sysGmm(g2, h2, data=wage, commonCoef=TRUE)
summary(res)

res2 <- sysGmm(g2, h2, data=wage)
summary(res2)
```

```

five(g2, h2, data=wage)

threeSLS(g2, h2[[1]], data=wage)

sur(g2, data=wage)

randEffect(g2, data=wage)

## Cross-Equation restrictions
## All but the intercept are assumed to be the same

res <- sysGmm(g2, h2, data=wage, crossEquConst = 2:4)
summary(res)

```

---

tsls

*Two stage least squares estimation*

---

## Description

Function to estimate a linear model by the two stage least squares method.

## Usage

```
tsls(g,x,data)
```

## Arguments

g	A formula describing the linear regression model (see details below).
x	The matrix of instruments (see details below).
data	A data.frame or a matrix with column names (Optional).

## Details

The function just calls `gmm` with the option `vcov="iid"`. It just simplifies the the implementation of 2SLS. The users don't have to worry about all the options offered in `gmm`. The model is

$$Y_i = X_i\beta + u_i$$

In the first step, `lm` is used to regress  $X_i$  on the set of instruments  $Z_i$ . The second step also uses `lm` to regress  $Y_i$  on the fitted values of the first step.

## Value

'tsls' returns an object of 'class' "tsls" which inherits from class "gmm".

The functions 'summary' is used to obtain and print a summary of the results. It also compute the J-test of overidentifying restriction

The object of class "gmm" is a list containing at least:

coefficients	$k \times 1$ vector of coefficients
residuals	the residuals, that is response minus fitted values if "g" is a formula.
fitted.values	the fitted mean values if "g" is a formula.
vcov	the covariance matrix of the coefficients
objective	the value of the objective function $\ var(\bar{g})^{-1/2}\bar{g}\ ^2$
terms	the <code>terms</code> object used when g is a formula.
call	the matched call.
y	if requested, the response used (if "g" is a formula).
x	if requested, the model matrix used if "g" is a formula or the data if "g" is a function.
model	if requested (the default), the model frame used if "g" is a formula.
algoInfo	Information produced by either <code>optim</code> or <code>nlminb</code> related to the convergence if "g" is a function. It is printed by the <code>summary.gmm</code> method.

## References

Hansen, L.P. (1982), Large Sample Properties of Generalized Method of Moments Estimators. *Econometrica*, **50**, 1029-1054,

## Examples

```
n <- 1000
e <- arima.sim(n,model=list(ma=.9))
C <- runif(n,0,5)
Y <- rep(0,n)
Y[1] = 1 + 2*C[1] + e[1]
for (i in 2:n){
Y[i] = 1 + 2*C[i] + 0.9*Y[i-1] + e[i]
}
Yt <- Y[5:n]
X <- cbind(C[5:n],Y[4:(n-1)])
Z <- cbind(C[5:n],Y[3:(n-2)],Y[2:(n-3)],Y[1:(n-4)])

res <- tsls(Yt~X,~Z)
res
```

---

vcov

*Variance-covariance matrix of GMM or GEL*

---

## Description

It extracts the matrix of variances and covariances from `gmm` or `gel` objects.

**Usage**

```
## S3 method for class 'gmm'
vcov(object, ...)
## S3 method for class 'gel'
vcov(object, lambda = FALSE, ...)
## S3 method for class 'tsls'
vcov(object, type=c("Classical", "HC0", "HC1", "HAC"),
      hacProp = list(), ...)
## S3 method for class 'ategel'
vcov(object, lambda = FALSE, robToMiss = TRUE, ...)
```

**Arguments**

object	An object of class <code>gmm</code> or <code>gmm</code> returned by the function <code>gmm</code> or <code>gel</code>
lambda	If set to <code>TRUE</code> , the covariance matrix of the Lagrange multipliers is produced.
type	Type of covariance matrix for the meat
hacProp	A list of arguments to pass to <code>kernHAC</code>
robToMiss	If <code>TRUE</code> , it computes the robust to misspecification covariance matrix
...	Other arguments when <code>vcov</code> is applied to another class object

**Details**

For `tsls()`, if `vcov` is set to a different value than "Classical", a sandwich covariance matrix is computed.

**Value**

A matrix of variances and covariances

**Examples**

```
# GMM #
n = 500
phi<-c(.2,.7)
thet <- 0
sd <- .2
x <- matrix(arima.sim(n = n,list(order = c(2,0,1), ar = phi, ma = thet, sd = sd)), ncol = 1)
y <- x[7:n]
ym1 <- x[6:(n-1)]
ym2 <- x[5:(n-2)]

H <- cbind(x[4:(n-3)], x[3:(n-4)], x[2:(n-5)], x[1:(n-6)])
g <- y ~ ym1 + ym2
x <- H

res <- gmm(g, x)
vcov(res)
```

```
## GEL ##  
  
t0 <- c(0,.5,.5)  
res <- gel(g, x, t0)  
vcov(res)  
vcov(res, lambda = TRUE)
```

---

wage

*Labor Data*

---

### Description

Data used to measure return to education by Griliches (1976)

### Usage

```
data(wage)
```

### Format

A data frame containing 20 cross-sectional vectors.

**AGE, AGE80** Age in 1969 and 1980 respectively

**EXPR, EXPR80** Working experience in 1969 and 1980 respectively

**IQ** IQ measure of the individual

**KWW** A test score

**LW, LW80** Log wage in 1969 and 1980 respectively

**MED** Mother education

**MRT, MRT80**

**RNS, RNS80**

**S, S80** Schooling in 1969 and 1980 respectively

**SMSA, SMSA80**

**TENURE, TENURE80** Tenure in 1969 and 1980 respectively

**YEAR**
